# Motivation

- ▶ **Question:** Which network topologies can assure high performance?

# Motivation

- ▶ **Question:** Which network topologies can assure high performance?
- ▶ Answer depends on how we measure performance:
  - ▶ Degree/diameter problem
  - ▶ Expandability, etc.

# Motivation

- ▶ **Question:** Which network topologies can assure high performance?
- ▶ Answer depends on how we measure performance:
  - ▶ Degree/diameter problem
  - ▶ Expandability, etc.
- ▶ We consider two measures:
  - ▶ minimum gossiping time
  - ▶ minimum edge-congestion for all-to-all routing

# Motivation

- ▶ **Question:** Which network topologies can assure high performance?
- ▶ Answer depends on how we measure performance:
  - ▶ Degree/diameter problem
  - ▶ Expandability, etc.
- ▶ We consider two measures:
  - ▶ minimum gossiping time
  - ▶ minimum edge-congestion for all-to-all routing
- ▶ What are the 'most efficient' graphs (of small degree) with respect to these measures?

# Routing

Design a transmission route (oriented path) for each ordered pair of vertices in a given network  $\Gamma = (V, E)$ .

- ▶ A set  $\mathcal{R}$  of such oriented paths is called an all-to-all **routing**.
- ▶ **Load of an edge** = number of paths traversing the edge in either direction
- ▶ **Load of an arc** = number of paths traversing the arc in its direction, an **arc** being an ordered pair of adjacent vertices

## Edge- and arc-forwarding indices

- ▶  $L(\Gamma, \mathcal{R}) =$  maximum load on an edge
- ▶ **Edge-forwarding index**  $\pi(\Gamma) = \min_{\mathcal{R}} L(\Gamma, \mathcal{R})$
- ▶ **Minimal e.f. index**  $\pi_m(\Gamma)$ : same as  $\pi(\Gamma)$  but use shortest paths only
- ▶  $\vec{L}(\Gamma, \mathcal{R}) =$  maximum load on an arc
- ▶ **Arc-forwarding index**  $\vec{\pi}(\Gamma) = \min_{\mathcal{R}} \vec{L}(\Gamma, \mathcal{R})$
- ▶ **Minimal a.f. index**  $\vec{\pi}_m(\Gamma)$ : same as  $\vec{\pi}(\Gamma)$  but use shortest paths only
- ▶ In general,

$$\pi_m(\Gamma) \neq \pi(\Gamma), \vec{\pi}_m(\Gamma) \neq \vec{\pi}(\Gamma)$$
$$\pi(\Gamma) \neq 2\vec{\pi}(\Gamma), \pi_m(\Gamma) \neq 2\vec{\pi}_m(\Gamma)$$

## Trivial lower bounds

$$\pi_m(\Gamma) \geq \pi(\Gamma) \geq \frac{\sum_{(u,v) \in V \times V} d(u,v)}{|E|}$$

Equalities  $\Leftrightarrow$  there exists an **edge-uniform shortest path routing**

## Trivial lower bounds

$$\pi_m(\Gamma) \geq \pi(\Gamma) \geq \frac{\sum_{(u,v) \in V \times V} d(u,v)}{|E|}$$

Equalities  $\Leftrightarrow$  there exists an **edge-uniform shortest path routing**

$$\vec{\pi}_m(\Gamma) \geq \vec{\pi}(\Gamma) \geq \frac{\sum_{(u,v) \in V \times V} d(u,v)}{2|E|}$$

Equalities  $\Leftrightarrow$  there exists an **arc-uniform shortest path routing**

## Trivial lower bounds

$$\pi_m(\Gamma) \geq \pi(\Gamma) \geq \frac{\sum_{(u,v) \in V \times V} d(u,v)}{|E|}$$

Equalities  $\Leftrightarrow$  there exists an **edge-uniform shortest path routing**

$$\vec{\pi}_m(\Gamma) \geq \vec{\pi}(\Gamma) \geq \frac{\sum_{(u,v) \in V \times V} d(u,v)}{2|E|}$$

Equalities  $\Leftrightarrow$  there exists an **arc-uniform shortest path routing**

### Question

**A:** Which graphs can achieve these bounds?

# Gossiping

Every vertex has a distinct message to be sent to all other vertices. Carry out this in minimum number of time steps.

$$t(\Gamma) = \text{minimum time steps}$$

under the **store-and-forward, all-port and full-duplex** model:

- ▶ a vertex must receive a message wholly before transmitting it to other vertices ('store-and-forward');
- ▶ 'all-neighbour transmission' at the same time step ('all-port');
- ▶ bidirectional transmission on each edge ('full-duplex');
- ▶ it takes one time step to transmit any message over an arc;
- ▶ no two messages over the same arc at the same time

## A trivial lower bound

For any graph  $\Gamma$  with minimum degree  $k$ ,

$$t(\Gamma) \geq \left\lceil \frac{|V| - 1}{k} \right\rceil.$$

## A trivial lower bound

For any graph  $\Gamma$  with minimum degree  $k$ ,

$$t(\Gamma) \geq \left\lceil \frac{|V| - 1}{k} \right\rceil.$$

### Question

**B:** *Which graphs can achieve this bound?*

# Frobenius groups

- ▶ A **Frobenius group** is a non-regular transitive group such that only the identity element can fix two points.
- ▶ (Thompson 1959) A finite Frobenius group  $G$  on  $V$  has a nilpotent normal subgroup  $K$  (**Frobenius kernel**) which is regular on  $V$ . Thus

$$G = K.H \text{ (semidirect product),}$$

where  $H$  is the stabiliser of a point of  $V$ .

- ▶ We may think of  $G$  as acting on  $K$  in such a way that  $K$  acts on  $K$  by right multiplication and  $H$  acts on  $K$  by conjugation.

# Frobenius graphs

## Definition

(Solé 94, Fang-Li-Praeger 98) Let  $G = K.H$  be a finite Frobenius group. Call  $\text{Cay}(K, S)$  a  **$G$ -Frobenius graph** if

$$S = \begin{cases} a^H, & |H| \text{ even or } |a| = 2 \quad [\text{first-kind}] \\ a^H \cup (a^{-1})^H, & |H| \text{ odd and } |a| \neq 2 \quad [\text{second-kind}] \end{cases}$$

for some  $a \in K$  such that  $\langle a^H \rangle = K$ .

## Partial answer to Question A

$d$ : diameter of  $\text{Cay}(K, S)$

$n_i$ : number of  $H$ -orbits of vertices at distance  $i$  from 1 in  $\text{Cay}(K, S)$ ,  $i = 1, \dots, d$

### Theorem

(Solé, Fang, Li and Praeger) Let  $\Gamma = \text{Cay}(K, S)$  be a Frobenius graph. Then

$$\pi(\Gamma) = \frac{\sum_{(u,v) \in V \times V} d(u,v)}{|E|} = \begin{cases} 2 \sum_{i=1}^d i n_i, & [\text{first-kind}] \\ \sum_{i=1}^d i n_i, & [\text{second-kind}] \end{cases}$$

## Theorem

(Z, 06) Let  $\Gamma = \text{Cay}(K, S)$  be a *first-kind Frobenius graph*. Then there exists a routing which is

- (a) a shortest path routing;
- (b)  $G$ -arc transitive;
- (c) both edge- and arc-uniform;
- (d) optimal for  $\pi, \vec{\pi}, \vec{\pi}_m, \pi_m$  simultaneously.

Moreover, if the  $H$ -orbits on  $K$  are known, we can construct such routings (not unique) in polynomial time. Furthermore, we have

$$\pi(\Gamma) = 2\vec{\pi}(\Gamma) = 2\vec{\pi}_m(\Gamma) = \pi_m(\Gamma) = 2 \sum_{i=1}^d in_i.$$

The formula for  $\vec{\pi}_m$  and a result of Diaconis-Stroock imply:

### Corollary

Let  $\Gamma, d, n_i$  be as above. Then

$$\lambda_2(\Gamma) \leq |H| - \frac{|K|}{d \sum_{i=1}^d in_i}.$$

## Partial answer to Question B

### Theorem

(Z, 06) Let  $\Gamma = \text{Cay}(K, S)$  be a *first-kind* Frobenius graph. Then

$$t(\Gamma) = \frac{|K| - 1}{|S|}.$$

Moreover, there exist optimal gossiping schemes such that

- (a) messages are always transmitted along shortest paths;
- (b) at any time every arc is used exactly once;
- (c) at any time  $\geq 2$  and for any vertex  $g$ , the set  $A(g)$  of arcs transmitting the message originated from  $g$  is a matching of  $\Gamma$ , and  $\{A(g) : g \in K\}$  is a partition of the arcs of  $\Gamma$ .

Furthermore, if we know the  $H$ -orbits on  $K$ , then we can construct such schemes (not unique) in polynomial time.

## Two families of first-kind Frobenius graphs

'Double-loop' network  $DL_n(a, b)$ :

Vertex set  $\mathbb{Z}_n$ ,  $x \sim x \pm a, x \sim x \pm b \pmod{n}$ , where  
 $n \geq 5, 1 \leq a \neq b \leq n-1, a, b \neq n/2, a+b \neq n$ .

'Triple-loop' network  $TL_n(a, b, 1)$ : Similar

## Theorem

(Thomson and Z, 08) If  $n \geq 6$  is even, then there exists no first kind Frobenius circulant graph of order  $n$  and valency four. If  $n = p_1^{e_1} \cdots p_l^{e_l} \geq 5$  is odd, the following are equivalent:

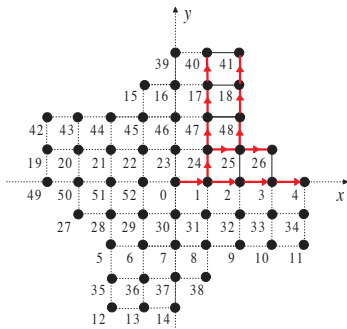

- (a)  $\exists h$  such that  $DL_n(1, h)$  is a first kind Frobenius graph;
- (b)  $x^2 + 1 \equiv 0 \pmod n$  has a solution;
- (c)  $p_i \equiv 1 \pmod 4$  for each  $i$ .

Moreover, if one of these holds, then

- (d) each solution  $h$  to  $x^2 + 1 \equiv 0 \pmod n$  gives rise to a first kind Frobenius  $DL_n(1, h)$ , and vice versa;
- (e) there are exactly  $2^{l-1}$  pairwise non-isomorphic 4-valent first kind Frobenius circulant graphs with order  $n$ , and each of them is isomorphic to some  $DL_n(1, h)$ .

				39	40	41			
			15	16	17	18			
42	43	44	45	46	47	48			
19	20	21	22	23	24	25	26		
49	50	51	52	0	1	2	3	4	
		27	28	29	30	31	32	33	34
			5	6	7	8	9	10	11
				35	36	37	38		
					12	13	14		

(a)

(b)

Optimal gossiping and routing in  $DL_{53}(1, 23)$ .

## Corollary

Let  $\Gamma = DL_{n_d}(1, 2d + 1)$  be the unique connected 4-valent circulant graph of diameter  $d \geq 2$  and maximum order  $n_d = 2d^2 + 2d + 1$  (Yebra-Fiol-Morillo-Alegre).

Then  $\Gamma$  is a  $\mathbb{Z}_{n_d}.H(d)$ -Frobenius graph, where

$$H(d) = \{[1], [2d + 1], -[1], -[2d + 1]\}.$$

Moreover,

$$\pi(\Gamma) = 2\vec{\pi}(\Gamma) = 2\vec{\pi}_m(\Gamma) = \pi_m(\Gamma) = \frac{d(d+1)(2d+1)}{3}$$

$$t(\Gamma) = \frac{d(d+1)}{2}.$$

## Theorem

(Thomson and Z, 09–10) There exists a 6-valent first kind Frobenius circulant  $TL_n(a, b, 1)$  of order  $n = p_1^{e_1} \cdots p_l^{e_l} \geq 7$  if and only if  $n \equiv 1 \pmod{6}$  and

$$x^2 - x + 1 \equiv 0 \pmod{n}$$

has a solution. Moreover, if these conditions hold, then

- (a) each solution  $a$  to the equation above gives rise to a first kind Frobenius  $TL_n(a, b, 1)$ , and vice versa, and in this case  $b \equiv a - 1 \pmod{n}$ ;
- (b) there are exactly  $2^{l-1}$  pairwise non-isomorphic 6-valent first kind Frobenius circulants of order  $n$ , and each of them is isomorphic to some  $TL_n(a, a - 1, 1)$ .

## Corollary

*The unique connected 6-valent circulant graph  $TL_{n_d}(3d + 1, 1, -(3d + 2))$  of diameter  $d \geq 2$  and maximum order  $n_d = 3d^2 + 3d + 1$  (Yebara-Fiol-Morillo-Alegre) is a first kind Frobenius graph.*

*Moreover,*

$$\pi(\Gamma) = 2\vec{\pi}(\Gamma) = 2\vec{\pi}_m(\Gamma) = \pi_m(\Gamma) = \frac{d(d+1)(2d+1)}{3}$$

$$t(\Gamma) = \frac{d(d+1)}{2}.$$

# Broadcasting time

## Theorem

(a) (Z, 10) *The broadcasting time of a Frobenius  $DL_n(1, h)$  is equal to  $\text{diam}(DL_n(1, h)) + 2$ .*

(b) (Thomson and Z, 09–10) *The broadcasting time of a Frobenius  $TL_n(a, a - 1, 1)$  is equal to  $\text{diam}(DL_n(1, h)) + 2$  or  $\text{diam}(DL_n(1, h)) + 3$ , and both cases can occur.*

# Gaussian graphs

## Definition

(Martínez, Beivide and Gabidulin 07) Let

$$\mathbb{Z}[i] = \{a + bi : a, b \in \mathbb{Z}\}$$

$$\mathbb{Z}[i]_\alpha = \mathbb{Z}[i]/(\alpha), \quad 0 \neq \alpha = a + bi, \quad \gcd(a, b) = 1$$

$$d_\alpha([\beta]_\alpha, [\gamma]_\alpha) = \min\{|x| + |y| : [\beta - \gamma]_\alpha = [x + yi]_\alpha\}$$

The **Gaussian graph**  $G_\alpha$  is defined to have vertex set  $\mathbb{Z}[i]_\alpha$  such that  $[\beta]_\alpha \sim [\gamma]_\alpha$  iff  $d_\alpha([\beta]_\alpha, [\gamma]_\alpha) = 1$ .

Thus

$$G_\alpha = \text{Cay}((\mathbb{Z}[i]_\alpha, +), H_\alpha)$$

where  $H_\alpha = \{[1]_\alpha, -[1]_\alpha, [i]_\alpha, -[i]_\alpha\}$ .

## Lemma

*(Z, 10) When the norm  $N(\alpha) = a^2 + b^2$  is odd,  $G_\alpha$  is a 4-valent Frobenius circulant, and vice versa.*

## Theorem

*(MBG 07; Thomson for odd  $N(\alpha)$ ) Suppose  $0 < a < b$  in  $\alpha = a + bi$  w.l.o.g. Then*

$$\text{diam}(G_\alpha) = \begin{cases} b, & \text{if } N(\alpha) \text{ is even} \\ b - 1, & \text{if } N(\alpha) \text{ is odd.} \end{cases}$$

# Eisenstein-Jacobi graphs

## Definition

(Martínez, Beivide and Gabidulin 07) Let

$$\rho = (1 + \sqrt{3}i)/2$$

$$\mathbb{Z}[\rho] = \{x + y\rho : x, y \in \mathbb{Z}\}$$

$$\alpha = c + d\rho \in \mathbb{Z}[\rho], \quad \gcd(c, d) = 1, \quad N(\alpha) = c^2 + cd + d^2 \geq 5$$

The **EJ-graph**  $EJ_\alpha$  is defined as the Cayley graph on  $(\mathbb{Z}[\rho]_\alpha, +)$  with respect to  $\{\pm[1]_\alpha, \pm[\rho]_\alpha, \pm[\rho^2]_\alpha\}$ .

## Lemma

*(Z, 10) The Frobenius circulant  $TL_n(a, a - 1, 1)$  is an EJ-graph.*

## Theorem

*(Flahive and Bose 10) Suppose  $a \geq b \geq 0$  w.l.o.g. Then*

$$\text{diam}(EJ_\alpha) = \frac{2a + b}{3}.$$

# How about second-kind F-graphs?

Let

$$\Gamma = \text{Cay}(K, S)$$

be a second-kind Frobenius graph, where  $G = K.H$  is Frobenius such that  $|H|$  is odd,  $S = a^H \cup (a^{-1})^H$  for some  $a \in K$  with  $|a| \neq 2$  and  $\langle a^H \rangle = K$ .

## Theorem

*(Fang and Z, 10) When  $K$  is abelian of odd order,  $\Gamma$  admits 'perfect' routing and gossiping schemes.*

*Otherwise, we only obtain an upper bound on the gossiping time and a 2-factor approximation algorithm.*

It is known that  $K$  is always abelian except when  $|H|$  is odd and all Sylow subgroups of  $H$  are cyclic.

# Paley graphs

## Definition

Let  $q \equiv 1 \pmod{4}$  be a prime. The Paley graph  $P(q)$  is the Cayley graph on  $(\mathbb{F}_q, +)$  w.r.t. the set of non-zero squares in  $\mathbb{F}_q$ .

$P(q)$  is a Frobenius graph (Solé).

# Near fields

A **near field** is like a field except that multiplication may not be commutative and there is only a one-sided distributive law.

A field is a near field, but the converse is not true.

For any near field  $(F, +, \cdot)$ ,  $(F, +)$  is an elementary abelian group  $\mathbb{Z}_p^n$ . In particular,  $|F| = p^n$  is a prime power.

# Generalized generalized Paley graphs

## Theorem

*(Fang and Z, 10) Let  $(F, +, \cdot)$  be a finite near field of odd order. Let  $\beta \in F^*$  and let  $H \neq 1$  be a subgroup of  $(F^*, \cdot)$  of odd order.*

*If the left coset  $\beta H$  of  $H$  in  $(F^*, \cdot)$  is a generating set of  $(F, +)$ , then  $\text{Cay}((F, +), \beta H \cup (-\beta H))$  is a second-kind Frobenius graph.*

# Generalized Paley graphs

## Definition

(Lim and Praeger 09) Let  $q = p^n$  and  $k \geq 2$  be a divisor of  $q - 1$  such that either  $q$  or  $(q - 1)/k$  is even. Let  $A \leq (\mathbb{F}_q^*, \cdot)$  with order  $(q - 1)/k$ . Define

$$\text{GPaley}(q, (q - 1)/k) = \text{Cay}((\mathbb{F}_q, +), A).$$

If  $q \equiv 1 \pmod{4}$ , then  $\text{GPaley}(q, (q - 1)/2) = P(q)$ .

If  $q$  is odd and  $\text{GPaley}(q, (q - 1)/k)$  is connected, then

$$\text{GPaley}(q, (q - 1)/k) \cong \text{Cay}((\mathbb{F}_q, +), 1A \cup (-1A))$$

which is a second-kind Frobenius graph. (Lim and Praeger: We know exactly when  $\text{GPaley}(q, (q - 1)/k)$  is connected.)

## Corollary

(Fang and Z, 10) Let  $\Gamma = \text{Cay}((F, +), \beta H \cup (-\beta H))$  be as before. Then

$$t(\Gamma) = (p^n - 1)/2|H|$$

and there exist optimal gossiping schemes for  $\Gamma$  such that

- (a) at any time  $t$  each arc of  $\Gamma$  is used exactly once for data transmission;
- (b) for each  $x \in K$ , exactly  $2|H|$  arcs are used to transmit messages with source  $x$ , and when  $t \geq 2$  the set  $A_t(x)$  of such arcs form a matching of  $\Gamma$ .

In particular,

$$t(\text{GPaley}(q, (q-1)/k)) = k$$

and (a)-(b) hold for  $\text{GPaley}(q, (q-1)/k)$ .

## An example

Let  $H = \langle 3^6 \rangle = \{3^6 = 7, 3^{12} = 11, 3^{18} = 1\} \leq \mathbb{F}_{19}^*$  (3 is a primitive element of  $\mathbb{F}_{19}$ ). Then

$$3H = \{7 \cdot 3 = 2, 11 \cdot 3 = 14, 3\}$$

is a generating set of  $(\mathbb{F}_{19}, +)$ . So

$$\Gamma = \text{Cay}(\mathbb{Z}_{19}, 3H \cup (-3H)) = \text{Cay}(\mathbb{Z}_{19}, \{2, 14, 3, 17, 5, 16\})$$

is a second-kind  $\mathbb{Z}_{19} \cdot \mathbb{Z}_3$ -Frobenius graph (but not a Lim-Praeger graph).

$$\pi(\Gamma) = 2\overrightarrow{\pi}(\Gamma) = 2\overrightarrow{\pi}_m(\Gamma) = \pi_m(\Gamma) = 1 \cdot 2 + 2 \cdot 4 = 10$$

$$t(\Gamma) = (19 - 1)/(2 \cdot 3) = 3$$

Finally ... degree-diameter ...

## Finally ... degree-diameter ...

### Proposition

(a) For any even integer  $\Delta \geq 2$ ,

$$N^{at}(\Delta, 2) \geq \frac{1}{4}(\Delta + 2)^2.$$

(b) For any  $0 < \varepsilon < 1$ , there exist infinitely many odd integers  $\Delta$  of the form  $q^3(q^{d-2} - 1)/(q - 1)$ , where  $q$  is an odd prime power and  $d \geq 3/\varepsilon$  is an odd integer, such that

$$N^{at}(\Delta, 2) > \Delta^{2-\varepsilon} + 2\Delta^{1-\frac{\varepsilon}{3}} + \Delta^{1-\frac{2\varepsilon}{3}} + 3.$$

## Finally ... degree-diameter ...

### Proposition

(a) For any even integer  $\Delta \geq 2$ ,

$$N^{at}(\Delta, 2) \geq \frac{1}{4}(\Delta + 2)^2.$$

(b) For any  $0 < \varepsilon < 1$ , there exist infinitely many odd integers  $\Delta$  of the form  $q^3(q^{d-2} - 1)/(q - 1)$ , where  $q$  is an odd prime power and  $d \geq 3/\varepsilon$  is an odd integer, such that

$$N^{at}(\Delta, 2) > \Delta^{2-\varepsilon} + 2\Delta^{1-\frac{\varepsilon}{3}} + \Delta^{1-\frac{2\varepsilon}{3}} + 3.$$

### Question

Are there infinitely many integers  $\Delta \geq 2$  such that

$$N^{at}(\Delta, 2) \geq \Delta^2 - f(\Delta)$$

for some function  $f$  with  $f(x)/x^2 \rightarrow 0$  as  $x \rightarrow \infty$ ?
